

# Sleeplog

## Build Session

### FORMAT

Live build, ~1 hour

### TOOLS

Bring whatever you use

### STACK

React Native (your setup)

## What this is

You're building Sleeplog — a mobile app where a parent can log their infant's nightly sleep and get an AI-powered weekly summary. It's a real, completable product idea with a data layer, an AI layer, and a UI that needs to feel good in someone's hand at 3am.

The session has three phases that build on each other.

We care more about how you think and make decisions than whether every pixel is perfect. Talk through tradeoffs as you go.

### One requirement

**The app must run on a real device or simulator before Phase 2 begins.**

Running in a browser is not acceptable.

## Timing

| Phase   | Target  | Deliverable                                               |
|---------|---------|-----------------------------------------------------------|
| 1       | ~25 min | Log screen with entry list and add form running on device |
| 2       | ~25 min | AI analysis screen with loading and result states         |
| 3 ♦     | ~10 min | Stretch — your choice (see Phase 3)                       |
| Debrief | ~10 min | Discussion, tradeoffs, what you'd do with more time       |

## PHASE 1

## Log Screen + Add Entry Sheet

A parent opens the app and sees a list of sleep entries for their infant. They can add a new entry with date, sleep time, wake time, and an optional note.

## BUILD

- A scrollable list showing logged sleep entries — date, time range, duration, and optional notes
- A sensible empty state for when there are no entries yet
- A way to add a new entry (the wireframes show the interaction pattern)
- The add form: date, sleep start time, wake time, and a notes field
- In-memory state only — no persistence needed yet

## DATA MODEL HINT

Each entry needs at minimum: a date, a sleep start time, a wake time, and optional notes. Computed duration is a nice-to-have.

## Design note

The wireframes are on the last page. They show the screens but don't label every interaction.

## PHASE 2

## AI Analysis Screen

A second tab — Analysis — sends the logged entries to an LLM and returns a structured summary. You need to handle loading, success, and error states.

## BUILD

- An Analysis tab in the bottom navigation
- On load: POST the entries to the Anthropic API and ask for a weekly summary
- Loading state — skeleton placeholders or a meaningful indicator (never a blank screen)
- Result state — a plain-language summary, at least two key stats, and one actionable tip

## API DETAILS

|          |                                                    |
|----------|----------------------------------------------------|
| Endpoint | <code>https://api.anthropic.com/v1/messages</code> |
| Model    | <code>claude-sonnet-4-20250514</code>              |
| API Key  | Will be provided at the start of the session       |

## Prompt craft matters

How you structure the prompt is part of the exercise. Think about what context the model needs to give a genuinely useful tip rather than a generic one.

## PHASE 3 ♦

## Stretch — Your Choice

Pick one thing that would make this app feel meaningfully more complete and build it. There's no right answer — pick something you can actually finish in the time.

## IDEAS

- Sleep duration bar chart — 7 nights at a glance
- Share card — a text or image summary the parent could send to a pediatrician
- Entry detail / edit — tap an entry to expand or modify it
- Something else — if you have a better idea, go for it

## Debrief

We'll save the last 10 minutes to talk through your decisions. These are the kinds of questions we'll ask — worth having an answer in your head as you build.

- 1 How would you make this persist across sessions?
- 2 This app could use several native platform features — Live Activities to show active sleep on the Lock Screen, push notifications to remind parents to log, or HealthKit to sync sleep data. Pick one and walk me through how you'd integrate it.
- 3 What would you do differently with two days instead of one hour?
- 4 What's the part of your code you're least happy with?

# Wireframes

These are the screens for Phase 1 and Phase 2. Your implementation doesn't need to match them exactly — treat them as a design direction, not a spec. Phase 3 is intentionally left open.

## PHASE 1 Log Screen + Add Entry Sheet

Parent opens the app and sees a list of sleep entries. They tap + to add a new one. A bottom sheet slides up with the form. Hand them these two screens. Do not explain anything — see if they figure out the interaction pattern.

App title + baby name/age badge  
Empty state with clear CTA  
FAB for add — always visible

Latest entry highlighted  
Duration bar as quick visual scan  
Optional notes inline

Bottom sheet — standard mobile pattern  
Date + time pickers (native or custom)  
Dim background behind sheet

## PHASE 2 AI Analysis Screen

Tapping the Analysis tab sends the logged entries to the model. Show them two states: loading (skeleton) and result. The result has a plain-language summary, two stats, and one tip card.

Progress bar + label while streaming  
Skeleton placeholders — never blank screen

Dark card for AI summary — visually distinct  
Stat grid — scannable at a glance  
Tip card warm-toned, feels like advice not warning
